

PROGRAM SYLLABUS

MASTER Data Science, IP Paris 2023-2024

PART 1	3
Practical Introduction to Machine Learning	4
An Introduction to Machine Learning Theory.....	5
Natural Language Processing	8
Deep Learning I	9
PART 1-2	10
Optimization for Data Science	11
Convex Analysis and Optimization Theory.....	13
High Dimensional Statistics	14
Non Parametric Estimation and Testing	15
Hidden Markov Models and Sequential Monte Carlo Methods.....	16
Big Data Framework.....	18
Monte Carlo Methods: from MCMC to Data-based Generative model	20
Statistical Learning Theory	22
Data Stream Processing	24
PART 2	25
DATA CAMP	26
Introduction to Operations Research	28
Introduction to Computer Vision	29
Introduction to Reinforcement Learning	30
High Dimensional Matrix Estimation	31
Partially Observed Markov Chains in Signal and Image.....	32
Law and Ethics of Artificial Intelligence	33
PART 2-3	34
Generalization Properties of Algorithms in ML.....	35
Advanced AI Methods for Graphs and NLP (ALTEGRAD)	37

PART 3	39
Causal Inference	40
Online Learning and Aggregation.....	42
Operations Research for Data Science.....	43
Cloud Data Infrastructure	45
Cooperative Optimization for Data Science.....	47
Deep Learning II	48
Audio and Music Information Retrieval	49
Big Data and Insurance Project	50
Structured Data : Learning and Prediction.....	51
Tail Events Analysis: Robustness, Outliers and Models for Extremes	52
Optimal Transport: Theory, Computations, Statistics, and ML applications	54
CAPSTONE Project.....	55
Machine Learning research seminar	56
Representation Learning for Computer Vision and Medical Imaging.....	58
Recent Developments in Responsible AI	59
Stochastic Approximation And Reinforcement Learning.....	61

PART 1

Practical Introduction to Machine Learning

Instructor: Rémi Flamary, Ekhine Irurozki

Credits: 3 ECTS

Grading : Practical session reports and oral

Numerus clausus: 60

Language : English

Syllabus : The objective of this course is to provide a practical introduction to the field of machine learning. We will discuss the different machine learning problems from unsupervised (dimensionality reduction, clustering and density estimation) to supervised (classification, regression, ranking). In this course we will introduce for each method the problem, provide its modeling as an optimization problem and discuss the algorithms that are used to solve the problem. The practical aspect of each method will also be discussed along with python code and existing implementations.

The course will be completed by practical sessions that will allow the students to implement the methods seen in the course on practical problems such as image classification and time series prediction (biomedical and climate data). The objective of the practical session will be not only to learn to use the methods but also to interpret their models and results with respect to the data and the theoretical models.

Course overview:

- Introduction
 - Machine learning problems
 - Knowing your data
 - Preprocessing
- Unsupervised learning
 - Dimensionality reduction and
 - Dictionary learning and collaborative filtering
 - Clustering and generative modeling
 - Generative modeling
- Supervised learning
 - Linear models and kernel methods for regression and classification
 - Nearest neighbors and bayesian decision
 - Trees and ensemble methods
- ML in practice
 - Find your problem
 - Model selection

An Introduction to Machine Learning Theory

Instructor: Stephan Cléménçon, Myrto Limnios

Credits: 3

Numerus clausus: 60

Language: French

Syllabus: Beaucoup d'applications modernes (génomique, finance, e-marketing, etc.) requièrent de manipuler et traiter des données de très grande dimension. La discipline qui développe et étudie des méthodes concrètes pour modéliser ce type de données s'appelle l'apprentissage statistique («statistical machine-learning»). Il s'agit, in fine, de produire des outils de prédiction et d'aide à la décision dédiés à une application spécifique. L'apparition d'algorithmes très performants pour la classification de données en grande dimension, tels que le boosting ou les Support Vector Machines dans le milieu des années 90, a progressivement transformé le champ occupé jusqu'alors par la statistique traditionnelle qui s'appuyait en grande partie sur le prétraitement réalisé par l'opérateur humain. En s'appuyant sur la théorie popularisée par Vapnik (The Nature of Statistical Learning, 1995), un nouveau courant de recherche est né: il se situe à l'interface entre les communautés mathématique et informatique et mobilise un nombre croissant de jeunes chercheurs tournés vers les applications liées à l'analyse de données massives. Dans ce module, on présentera le domaine, ses fondements théoriques, les problèmes qu'il permet d'aborder (apprentissage supervisé/non supervisé, batch/online, par renforcement, multi-tâche, asynchrone, etc.) et les approches algorithmiques les plus populaires.

«Nothing is more practical than a good theory» - V. Vapnik

Format: 6 sessions of lessons/practical lessons of 3h (1h30+1h30)

L'objectif du cours est de découvrir les enjeux et paradigmes du "machine learning", une discipline en plein essor à l'interface des mathématiques (probabilités/ statistiques, optimisation) et de l'informatique et qui joue aujourd'hui un rôle majeur en matière d'innovation technologique. Il s'agira ici d'en explorer quelques concepts et techniques essentiels, principalement autour du problème fondamental de la "classification supervisée" (i.e. "reconnaissance de formes"). Il se déroulera sur six séances de 3h incluant:

- une partie 'cours magistral' lors de laquelle seront formulés les problèmes et décrites certaines solutions de l'état de l'art ;
- une partie 'travaux dirigés' pour les séances d'exercices.

Séance 1 - 20/09:

- Introduction générale du cours : repères historiques, enjeux, applications, nomenclature des problèmes
 - Le problème de la classification binaire (reconnaissance de formes) : Formalisme – Optimalité
- Lectures conseillées: Chapitre 2 de (1), Chapitres 1 et 2 de (9), article (4)

Séance 2 - 27/09

- Théorie probabiliste de la classification - Minimisation empirique du risque
- Théorie de Vapnik-Chervonenkis – Complexité combinatoire - Moyennes de Rademacher
- Exercices Lectures conseillées: articles (3) et (4)

Séance 3 - 04/10

- Premières stratégies d'apprentissage supervisé, modélisation et moyennes locales: régression logistique - perceptron - arbres de classification – K-plus proches voisins - réseaux de neurones
- Lectures conseillées: Chapitres 4 et 9 de (1)

Séance 4 - 11/10

- Evaluation de l'erreur et sélection de modèles : plan expérimental – bootstrap – validation croisée – minimisation structurelle du risque • Ensemble Learning: Bagging, Boosting et Forêts Aléatoires
- Lectures conseillées: Chapitre 7 de (1)

Séance 5 - 18/10

- Les machines à vecteurs support (SVM) : linéaires/non linéaires
- «Kernel trick»: ACP, régression Lectures conseillées: (8) et (9) Séance 6 - 25/10
- Au delà des problèmes d'apprentissage 'locaux' (classification, regression, estimation de densité): clustering, ranking, détection d'anomalies

Natural Language Processing

Instructors: Maria Boritchev, Chloé Clavel, Matthieu Labeau

Credits: 6 ECTS

Grading: Practical session reports (60%) and Exam (40%).

Numerus clausus: 60

Language: English

Description: Natural Language Processing (NLP) is a very important field of research, which we can find applications of everywhere. During the last decade, deep Learning has profoundly transformed the way we do NLP, bringing huge performance gains in many traditional tasks involving natural language thanks to end-to-end neural models - relying mainly on the availability of textual data. The goal of this course is to provide students with (1) a theoretical understanding of modern NLP models through a review of the most important milestones in recent NLP (2) a practical understanding of the difficulties of performing machine learning tasks on natural language, and how to apply NLP techniques in novel circumstances.

Schedule:

- Lecture 1 - 15/09 - Introduction to Text Processing and Symbolic Text Representations
- Lecture 2 – 22/09 - Introduction to Language Modeling and Text Generation
- Lab 1 – 29/09 - Character n-gram Language Models and applications
- Lecture 3 – 06/10 - Word Embeddings, Algorithms and Applications
- Lab 2 – 13/10 - Topic modeling and classification
- Lecture 4 – 20/10 - Sequence models, Encoders and Decoders
- Lecture 5 - 10/11 - Structured Prediction in Natural Language Processing
- Lecture 6 – 17/11 - Contextual Representations and Transfer Learning for Natural Language Processing Tasks
- Lab 3 - 24/11 - Word sense disambiguation
- Lecture 7 – 01/12 - Sentiment Analysis : towards transparent models
- Lab 4 - 08/12 - Sentiment Analysis with modern NLP tools
- Exam - 15/12

References: Slides will be available. For more details, we will refer for lectures to relevant chapters of the following books (available online):

- [Natural Language Processing](#), Jacob Eisenstein
- [Speech and Language Processing](#), Dan Jurafsky and James H Martin

Deep Learning I

Instructors: Geoffroy Peeters, Loïc Le Folgoc (Télécom Paris, IP-Paris)

Credits: 3 ects

Grading : 30% labs/project + 70% written exam

Language: English

Syllabus: Deep Learning (machine learning based on deep artificial neural networks) has become extremely popular over the last years due to the very good results it allows for tasks such as regression, classification or generation. The objective of this course is to provide a theoretical understanding and a practical usage of the three main types of networks (Multi-Layer-Perceptron, Recurrent-Neural-Network and Convolutional Neural Network). The content of this course ranges from the perceptron to the generation of adversarial images. Each theoretical lecture is followed by a practical lab on the corresponding content where student learn to implement these networks using the currently three popular frameworks: pytorch, tensorflow and keras.

Lectures content:

- Multi-Layer-Perceptron (MLP): Perceptron, Logistic Regression, Chain rule, Back-propagation, Deep Neural Activation functions, Vanishing gradient, Initialization, Regularization (L1, L2, DropOut), Alternative Gradient Descent, Batch-normalization
- Recurrent Neural Network (RNN) : Simple RNN, Forward Propagation, Backward Propagation Through Time, Vanishing/ Exploding gradients, Gated Units (LSTM, GRU), Various architectures, Sequence-to-sequence, Attention model
- Convolutional Neural Network (CNN) : CNNs use sparse connectivity and weight sharing to reduce parameters and create more powerful networks , connections are organized in a convolution operation, CNNs now provide the state-of-the-art in a vast array of problems, we will see how CNNs work and we will implement them for classification problems

Labs content :

- text recognition, sentiment classification
- music generation
- image recognition
- image generation

Programming language

- Python (numpy, scikit-learn, matplotlib)
- DL frameworks: pytorch, tensorflow, keras
- Use Télécom computers, your own labtop or colab.research.google.com → needs a Google account → open one before the first Lab !
- a Graphics Processing Unit (GPU) will not be required, however if you have one, this will speed up the learning process

PART 1-2

Optimization for Data Science

Instructors: Alexandre Gramfort, Hicham Janati

Credits: 6 ects

Grading:

Labs. 2-3 Labs with Jupyter graded (30% of the final grade).

Project. Implementation of solvers for a machine learning model. 30% of final grade.

Exam. 3h Exam (40% of the final grade).

Language: English

Syllabus : Modern machine learning heavily relies on optimization tools, typically to minimize the so called loss functions on training sets. The objective of this course is to cover the necessary theoretical results of convex optimization as well as the computational aspects. This course contains a fair amount of programming as all algorithms presented will be implemented and tested on real data. At the end of the course, students shall be able to decide what algorithm is the most adapted to the machine learning problem given the size of the data (number of samples, sparsity, dimension of each observation).

Planning:

- Week 1 Lecture: Motivation: Why ML leads to optimization problems? Foundations of convex optimization: gradient, sub-differential, strong convexity, conditioning. Recap on linear algebra, Exercise list : Convexity and smoothness
- Week 2 Lecture: First order algorithms: gradient descent for smooth functions (strongly and non-strongly convex cases), convergence proofs in the smooth and smooth + strongly convex case.
- Week 2 Lecture: Proximal algorithms, proximal gradient descent + acceleration, Introduction to the Lasso and sparse linear models
- Week 4 Lab 1
- Week 5 Lecture: Stochastic algorithms, SGD, with and without momentum, convex, strongly convex, with proofs.
- Week 6 Lecture: Stochastic variance reduced methods (SAGA, SVRG) with numerical tricks: lazy updating, sparse tricks. Exercise list : Variance reduction
- Week 7: Lab 2
- Week 8 Lecture + short Lab: Coordinate descent algorithms, Lab on coordinate descent implementation on logistic and ridge

- Week 9: Lecture: Solvers for quadratic functions (SVD, Woodbury matrix inversion lemma), conjugate gradient (dense vs sparse data). Line search methods.

- Week 10: Exercises

- Week 11 Lecture + Short Lab: Second order methods: Newton, Quasi-Newton (BFGS, L-BFGS). Illustration of convergence problem of Newton, initialisation, construction of BFGS et L-BFGS. Lab: implementation of Newton and quasi-Newton methods.

- Week 12 Lecture: Non-convex and beyond convexity (adaptive Lasso / SCAD), Frank-Wolfe. Majorization-Minimization approaches

Convex Analysis and Optimization Theory

Instructor: Pascal Bianchi, Olivier Fercoq and Walid Hachem

Credits: 6 ETCS

Grading: Final exam

Language: English

Syllabus: The course is not intended to provide a repertoire of algorithms as abundant as possible. It is about taking a step back in order to understand the mathematical foundations for the construction of a large class of iterative methods. The first part of the course is about convex analysis. We shall review the properties of convex functions, Fenchel-Legendre transform, and introduce the student to the duality theory in convex optimization. The second part of the course is about numerical algorithms. We shall see the conditions under which we can demonstrate the convergence of fixed point algorithms. This general approach makes it possible to obtain, as a corollary, the convergence of several emblematic algorithms such as the proximal gradient algorithm, or primal-dual algorithms. These algorithms are frequently used to solve optimization problems involving complex and structured regularizations, or optimization problems under constraints. They are frequently encountered in statistical learning, signal processing, and image processing. The objectives of the course are:

- Master the mathematical tools for the construction of optimization algorithms.
- Know how to demonstrate the convergence of iterates.
- Know how to numerically solve optimization problems involving non-differentiable terms and/or structured regularization.

High Dimensional Statistics

Instructor: Alexandre Tsybakov

Credits: 3 ects

Grading: Final exam

Numerus clausus: 15

Language: English

Syllabus: This course develops tools to analyze statistical problems in high-dimensional settings where the number of variables may be greater than the sample size. It is in contrast with the classical statistical theory that focuses on the behavior of estimators in the asymptotics as the sample increases while the number of variables stays fixed. We will show that, in high-dimensional problems, powerful statistical methods can be constructed under such properties as sparsity or low-rankness. The emphasis will be on the non-asymptotic theory underlying these developments.

Topics covered:

- Sparsity and thresholding in the Gaussian sequence model.
- High-dimensional linear regression: Lasso, BIC, Dantzig selector, Square
- Root Lasso. Oracle inequalities and variable selection properties.
- Estimation of high-dimensional low rank matrices. Matrix completion.
- Inhomogeneous random graph model. Community detection and estimation in the stochastic block model.

Prerequisites: Solid knowledge of probability theory, mathematical statistics, linear algebra. Notions of convex optimization.

Resources:

Alexandre Tsybakov. High-dimensional Statistics. Lecture Notes.

Non Parametric Estimation and Testing

Instructor: Cristina Butucea

Credits: 3 ects

Grading: Final exam

Language: English

Syllabus:

L. Devroye: A Course in Density Estimation. Birkhauser, Boston, 1987.

E. Giné, R. Nickl: Mathematical Foundations of Infinite-Dimensional Statistical Models, Cambridge University Press, 2015

A.Nemirovski: Topics in non-parametric statistics. Ecole d'Eté de Probabilités de Saint-Flour XXVIII – 1998. Lecture Notes in Mathematics, v.1738. Springer, 2000.

A.B.Tsybakov: Introduction to Nonparametric Estimation. Springer, New York, 2009.

L. Wasserman: All of Nonparametric Statistics. Springer, New York, 2006.

Hidden Markov Models and Sequential Monte Carlo Methods

Instructor: Chopin Nicolas

Credits: 3 ects

Grading : Project-based (group of three students)

Language: English

Syllabus: So-called hidden Markov chain (or state-space) models are time series models involving a "signal" (a Markov process $\{X_t\}$ describing the state of a system) observed in an imperfect and noisy way in the form of data, e.g. $Y_t=f(X_t)+\epsilon_t$. These models are widely used in many disciplines:

- Finance: stochastic volatility (X_t is the unobserved volatility)...
- Engineering: target tracking (X_t is the position of a mobile whose trajectory we are trying to find; speech recognition (X_t is a phoneme).
- Biostatistics: Ecology (X_t =population size); Epidemiology (X_t =number of infected).

The aim of this course is to present modern methods of sequential analysis of such models, based on particle algorithms (Sequential Monte Carlo). The problems of filtering, smoothing, prediction, and parameter estimation will be discussed. At the end of the course, we will also briefly discuss the extension of such algorithms to non-sequential problems, notably in Bayesian Statistics.

At the end of the course, the student will be able to:

- state the main properties of HMM models
- implement a particle filter to filter and smooth a given HMM model
- estimate the parameters of such a model from different methods

Planning:

1. Introduction: definition of HMM (Hidden Markov models), main properties, notion of filtering, smoothing and prediction, forward-backward formulas.
2. Discrete HMMs, Baum-Petrie's algorithm
3. Gaussian linear HMM, Kalman algorithm
4. SMC algorithms for filtering an HMM model
5. Estimation in HMM models
6. Introduction to non-sequential applications of SMC algorithms

Prerequisites:

- 2A Simulation and Monte Carlo or similar course
- 3A courses of "Computational Statistics" and "Bayesian Statistics" are recommended but not mandatory.

Big Data Framework

Instructor: Duc Pham Hi

Credits: 6 ECTS

Grading: The final mark of the module is a weighted average of 3 marks:

- Big Data with Hadoop (weight 5)
- Data Science with Spark (weight 3)
- Real Time Big Data Search and Analytics with Elastic Search (weight 2)

The first course is evaluated by an exam (1 hour) and a continuous evaluation (labs and mini-projects). The 2 last courses have a final exam (or a project, depending on students' orientations) only.

Numerus clausus: 30

Language: English

Syllabus: The objectives of this course are the following:

- Discover the different components of a Big Data cluster and how they interact.
- Understand Big Data paradigms.
- Understand the benefits of open source solutions.
- Develop a Big Data project from scratch
- Master Spark, its data models and its different methods of operation
- Learn how to use Spark to analyze data, develop Machine Learning pipelines and finally do streaming with Spark
- Understand and implement distributed algorithms.
- Understand the advantages of SQL/NOSQL databases.

Description of the course:

The module Big Data Frameworks is composed of three courses :

- Big Data with Hadoop (5 x 4 hours)
- Data Science with Spark (3 x 4 hours)
- Real Time Big Data Search and Analytics with Elastic Search (2 x 4 hours)

Big Data with Hadoop:

Apache Hadoop has been evolving as the Big Data platform on top of which multiple building blocks are being developed. This course presents the Hadoop ecosystem, Hadoop Distributed File System (HDFS) as well as many of the tools developed on it:

- MapReduce and YARN
- Hive and HBase
- Kafka, Flume, NiFi, Flink, Oozie, etc.

Students will also discover various subjects such as security, resource allocation and data governance in Hadoop.

Data Science with Spark:

Apache Spark is rapidly becoming the computation engine of choice for big data. This course presents:

- Spark's architecture and Spark Core: RDDs (Resilient Distributed Datasets), Transformations,

and Actions

- Spark and Structured Data: explore Spark SQL and Spark Data Frames
- Spark Machine Learning libraries (MLLIB and ML)
- Spark Streaming

Real time Elastic search and Analytics

Powerful tool to analyze in real time tons of data available to provide insights to business.

Use cases:

- Search (Wikipedia, Github), Logging Analytics (Blizzard), Security Analytics (Slack), Metrics Analytics (NASA), Business Analytics (Tinder)
- High availability and Speed
- Elastic Stack:
- Collect (Beat)
- Ingest (Logstash)
- Store, search and analytics engine (Elasticsearch)
- Visualize (Kibana)
- The secret sauce of ES, Index, Shards (Primary, Replicas), Nodes, Cluster, Cross-Cluster
- Typical deployment in key use cases (search, logging, security)

Prerequisites:

Java, Python, Machine Learning and basic knowledge in Linux system administration and SQL.

Monte Carlo Methods: from MCMC to Data-based Generative model

Instructors : Randal Douc & Emmanuel GOBET & Alain DURMUS

Credits: 6 ECTS

Grading: written exam (50%) and simulation project (50%)

Numerus Clausus: 30

Language: English

Syllabus:

This course on Monte Carlo methods is devoted to random simulation, and it is made of two parts among the most active and innovative topics in Monte Carlo methods.

Markov Chain Monte Carlo (MCMC)

For the past few years, statistical learning and optimization of complex dynamical systems with latent data have been applied to time series analysis across a wide range of applied science and engineering domains such as signal processing, target tracking, enhancement and segmentation of speech and audio signals, inference of ecological networks, etc.

Solving Bayesian nonlinear filtering and smoothing problems, i.e. computing the posterior distributions of some hidden states given a record of observations, and computing the posterior distributions of the parameters is crucial to perform maximum likelihood estimation and prediction of future states of partially observed models. Estimators of these posterior distributions may be obtained for instance with Sequential Monte Carlo (SMC), also known as particle filtering and smoothing, and Markov Chain Monte Carlo (MCMC) methods.

The first part of this Monte Carlo methods course sets the focus on MCMC algorithms and provides an overview of such approaches: introduction to standard procedures, convergence properties of a few algorithms and practical extensions (with simulations based on Python Notebooks) to more complex solutions.

Topics covered:

- Markovian models (specific focus on observation-driven models).
- Introduction to Markov chain Monte Carlo algorithms.
- Some convergence results of Markov chain Monte Carlo algorithms.
- Pseudo-Marginal MCMC and applications.
- Hamiltonian Monte Carlo algorithms and variants.
- Introduction to variational methods.

Generative models

A new paradigm of generative models has emerged in AI in the last decade. It aims at designing a generative model mimicking a distribution described by a data set. It has mainly two applications: data

augmentation, i.e. to generate new data statistically coherent with those of the initial (training) data set; digital twin, i.e. to replace a costly physical simulation model with an easy-to-use one. This has huge applications in image generation, fashion pictures, chemical molecules... this is called sometimes deepfakes.

A generative model is usually made of a random input (the latent space) and of a deterministic transformation function (usually made of neural networks) mapping the latent space into the data space.

In the second part of this Monte Carlo methods course, we will describe how to mathematically model and solve this problem, starting from basic concepts and going to more advanced tools. We will investigate (with mathematical tools)

- how to measure the distance between probability distributions, the relations between these distances
- existence of transformation between two given distributions
- the design of the optimization problem of the generative model
- possible parameterizations based on GAN, VAE, SDE
- role of the latent dimension in the search for a numerical solution, quality/complexity bounds on examples
- some statistical analysis for the sampling effect

Statistical Learning Theory

Instructor: Jaouad Mourtada (ENSAE)

Credits: 3 ects

Grading: Final exam. An exercise sheet (with exercises in the spirit of the exam) will be provided, and will be partly corrected in class.

Numerus Clausus: 50

Language: English

Syllabus: Supervised statistical learning refers to the following prediction problem: find a good rule to predict some output/label of interest (for instance, the object represented by an image), based on some associated input/features (for instance, the image itself), using a dataset of feature-label pairs. This is a core machine learning problem, with applications to computer vision, speech recognition and natural language processing, among many domains.

The aim of this course is to provide an introduction to the theory and principles underlying this general problem. The emphasis will be placed on mathematical and conceptual aspects, rather than on actual implementation: the key concepts and ideas will be illustrated through formal (often elementary) results, which will be proven in class.

Along the way, we will introduce some technical tools relevant in statistics and machine learning theory, including basic concentration inequalities and control of empirical processes, stochastic gradient methods, and approximation properties of some classes of functions.

Topics covered:

- Probabilistic setting: prediction, loss and risk;
- Universal consistency and No Free Lunch theorem;
- Empirical risk minimization and its analysis via uniform convergence. Approximation and estimation errors, overfitting and underfitting;
- Finite classes and Hoeffding's inequality; Rademacher complexity and Vapnik-Chervonenkis classes (upper and lower bounds);
- Model selection: complexity regularization and cross-validation;
- Nonparametric regression by histograms, bias-variance decomposition and convergence rates over Hölder classes; curse of dimension;
- Convex surrogate losses and their properties; Linear prediction, stochastic gradient methods; Links between regularization and optimization;
- Learning in high dimension and neural networks: approximation of 2-layer networks, interpolation and overfitting for linear regression.

Prerequisites: Knowledge of probability theory at an undergraduate level. Some notions in statistics (at the level of a first course in mathematical statistics) would be helpful, though this is not a strict requirement. Some general background in machine learning would also be a plus, though none is required to follow this course.

Data Stream Processing

Instructor: Jérémie Sublime – Mauras Todge – Maryam Barry

Credits: 6 ects

Grading:

- The practical sessions will make $\frac{2}{3}$ of the mark
- The research paper presentation will make $\frac{1}{3}$ of the mark

Language: English

Syllabus: This course deals with the algorithms and softwares commonly used to process large data streams. It aims at understanding the main difficulties and specificities of this type of data, knowing what different types of streams exist, what are the theoretical models and practical algorithms to analyze them, and what are the right tools to process these streams.

After an introduction of what data streams are from a conceptual point of view, this class covers the question of data stream processing from two different angles:

1. A Machine Learning and Data Mining approach to cover the theoretical and algorithmic difficulties of learning from data streams: online learning vs incremental and batch learning, and sampling techniques.
2. A more practical approach with an introduction to the various systems and software that are used to handle these data.

In terms of organization, the course will consist of an alternance of lectures and practical sessions. Finally, during the last class the students will have to present a recent research article of their choice on the subject of data stream processing.

Objectives :

- Introduction to the concept of data stream processing
- Learning the basics on and how to use Data Stream Management Systems (DSMS)
- Understanding the main sampling techniques used for stream processing : sampling, sketching, etc.
- Understanding and using the main data stream processing algorithms

Prerequisites :

- Basics in SQL language
- Basics in Machine Learning (supervised and unsupervised)
- A knowledge of Java programming is recommended but not mandatory

PART 2

DATA CAMP

Instructor: Thomas Moreau, Pedro Rodrigues et Alexandre Gramfort

Credits: 3 ects

Grading: Assignments, data challenge and project

Language: English

Syllabus: a 5-day intensive course on data science in practice.

Description:

The aim of this course is to learn data science by doing. All aspects of completing a data science pipeline will be covered, from exploratory data analysis (EDA), feature engineering, parameter optimization to advanced learning algorithms. To put this in practice, you will **compete on a set of data challenges**, and you will also need to **propose your own challenge!** On GitHub you have some of the [teaching materials](#). You **must** have a GitHub account to complete the course. Grade is a mix of your performance on the data challenge offered to the class as well as the challenge you will setup.

Each day you will have 50% of lectures and 50% of work on the competitive challenge using the [RAMP](#) website.

Day 1: Data wrangling

- Introduction to the workflow (VSCode, git, github, tests, ...)
- Advanced course on Pandas
- Assignments: [numpy](#) and [pandas](#) assignments using github.

Day 2: ML Pipelines and model evaluation

- Advanced scikit-learn: Column transformer and pipelines
- Parallel processing with joblib
- Generalization and Cross Validation
- Assignment: create your own scikit-learn estimator and cross-validation splitter.
- *Getting started on RAMP and introduction to the challenges.*

Day 3: Metrics and dealing with unbalanced data

- Presentation of the different ML metrics
- Problem of the metric with imbalanced data
- ML approaches to deal with imbalanced data
- *Working on data challenges*

Day 4: Feature engineering and model inspection

- Feature engineering and advanced encoding of categorical features
- Model inspection: Partial dependence plots, Feature importance
- *Working on data challenges*

Day 5: Ensemble methods and hyperparameter optimization

- From trees to gradient boosting
- Profiling with snakeviz
- Hyperparameter optimization
- *Working on data challenge*

Introduction to Operations Research

Instructor: Eric Soutil

Credits: 3 ects

Grading: final exam

Language: French

Syllabus: La Recherche Opérationnelle (R.O.) est la discipline des méthodes scientifiques utilisables pour élaborer de meilleures décisions. Elle permet de rationaliser, de simuler et d'optimiser l'architecture et le fonctionnement des systèmes de production ou d'organisation. La R.O. apparaît comme une discipline-carrefour associant les mathématiques, l'économie et l'informatique. Les apports de la R.O. sont visibles dans les domaines les plus divers : de l'organisation des lignes de production de véhicules à la planification des missions spatiales, de l'optimisation de portefeuilles bancaires à l'aide au séquençage de l'ADN ou à l'organisation de la couverture satellite des téléphones portables...

Tous ces problèmes sont de nature discrète ou combinatoire. Si l'existence d'une solution optimale est en général triviale, sa recherche de manière énumérative, même effectuée par les ordinateurs les plus puissants, pourrait demander plusieurs siècles de calcul.

Le but du cours est de présenter des problématiques d'optimisation combinatoire ainsi que des algorithmes efficaces pour leur résolution. Nous verrons ainsi des problématiques d'optimisation dans les graphes (arbres couvrant de poids maximal, plus court chemin, voyageur de commerce et flot maximal) ainsi que la programmation linéaire continue et en nombres entiers. Des TP seront dédiés à l'implémentation de certains des algorithmes considérés.

Prerequisites: None

Introduction to Computer Vision

Instructor: Alasdair Newson

Credits: 3 ects

Grading: lab work evaluation

Language: English

Syllabus: Image processing and Computer Vision are among the most common applications of data science. This is due to the fact that images and videos are particularly complex, and live in high dimensions. Therefore, tools to analyse and understand these objects are of great use to any data scientist studying them. These tools, which have existed before the advent of deep learning, look at images on a local scale and a global scale. The local scale corresponds to low-level information such as the colour of a pixel or the gradient in an image at a certain point. This is what we call image processing. Image processing is a pre-requisite for computer vision, which corresponds to understanding an image on a global level. In this case, we will be interested in detecting and understanding objects (faces for example) in images, to see what is happening in a scene. Such objects can be seen as collections of pixels, thus the more global viewpoint.

In this course, we will look at some of the classical tools to understand images. Firstly, we will go over basic sampling theory, used in signal processing. We will then look at filtering, radiometry, colour spaces and mathematical morphology. In the second lesson, we will look at computer vision, that is to say high level understanding of images. We will look at segmentation, basic feature detection (corners, lines etc), object detection and motion estimation. Finally, we will look at some more advanced topics in computer vision and image processing.

We will implement the algorithms seen in the lesson in lab works, carried out in the python programming language, with jupyter notebooks.

Format: 5 sessions

Course content:

- image sampling and filtering
- histogram equalisation
- image restoration
- image segmentation
- motion estimation

Programming language: Python, in the form of Jupyter Notebooks

Introduction to Reinforcement Learning

Instructor: Erwan LE PENNEC

Credits: 3 ects

Grading: Project based on a research article.

Language: English

Syllabus: This 20-hour course provides an introduction to reinforcement learning. It is based on the new edition of the book "Reinforcement Learning: An Introduction" by R. Sutton and A. Barto. Barto (available online at <http://incompleteideas.net/book/the-book-2nd.html>).

Outline:

1. Introduction to reinforcement learning and Markov decision processes
2. The bandit case
3. Tabular methods: prediction by dynamic programming, Monte Carlo method and TD Learning
4. Planning and learning for tabular methods
5. Approximate methods: prediction, planning and learning

High Dimensional Matrix Estimation

Instructor: Karim Lounici

Credits: 3 ects

Grading: final exam, article

Numerus Clausus: 30

Language: English

Syllabus : Nowadays many data learning problems require to analyze the structure of a high-dimensional matrix with remarkable properties; In recommender systems, this could be a column sparse matrix or a low-rank matrix but more sophisticated structures could be considered by combining several notions of sparsity; In graph analysis, popular spectrum techniques to detect cliques are based on the analysis of the Laplacian matrix with specific sparse/low-rank structure. In this course, we will review several mathematical tools useful to develop statistical analysis methods and study their performances. Such tools include concentration inequalities, convex optimization, perturbation theory and minimax theory.

Topics covered:

1. Principal Component Analysis
2. Spectral clustering
3. Matrix completion
4. Robust Statistics
5. Phase Retrieval
6. Optimal Transport

Partially Observed Markov Chains in Signal and Image

Instructor: Wojciech PIECZYNSKI

Credits: 3 ects

Grading: Quiz, project based on a research article

Language: French

Syllabus:

Les modèles de Markov partiellement observés (MMPO) admettent de multiples applications dans des domaines les plus divers. Les modèles de Markov cachés (MMC), qui sont des MMPO de base, apparaissent comme les modèles parmi les plus simples permettant une recherche des réalisations des processus cachés à partir des processus observés dans les cas de grandes masses de données. Les calculs séquentiels – donc explicites et rapides - sont permis par la nature markovienne du couple (processus caché, processus observé).

Dans la première partie du cours on s'intéressera aux processus cachés discrets. On passera en revue les modèles classiques que sont les chaînes, les arbres, et les champs de Markov cachés. On précisera les traitements bayésiens correspondants, ainsi que l'estimation des paramètres permettant des traitements non supervisés. Par la suite, on exposera diverses extensions des Markov cachés classiques - semi-Markov cachés, Markov couples, Markov triplets, Markov évidentiels - dont certains récents. On proposera des illustrations en segmentation statistique d'images, qui est un problème important en traitement d'images. Dans la deuxième partie on s'intéressera aux processus cachés continus. L'exposé des systèmes gaussiens classiques, rendant possible les filtrages optimaux de type Kalman, sera suivi par les descriptions des modélisations plus complexes de type Markov couple et Markov triplet. En particulier, on étudiera les systèmes à sauts permettant de faire un lien avec la première partie du cours. L'intérêt des notions traitées sera illustré par des applications en poursuite.

Une troisième partie, brève, contiendra des notions des machines de Boltzmann et des réseaux de connaissances profonds, qui peuvent être vues comme des modèles de Markov partiellement observés particuliers.

Law and Ethics of Artificial Intelligence

Instructor: Winston Maxwell and Tiphaine Viard

Credits: 3 ects

Grading: 50% quiz, 50% final paper and presentation, with possible adjustment of final grade, up or down one point out of 20, based on class participation

Language: English

Students will learn:

- why different families of AI (symbolic, machine learning, foundation models) present different risk profiles and require different approaches to regulation; discussion of systemic risks to democracy and national security
- AI ethics principles: what do they mean and do they serve a purpose?
- how risks of bias and discrimination manifest themselves in AI systems, and approaches to mitigate those risks; why achieving perfect fairness is impossible; introduction to human cognitive biases and why computers may be less (or more) discriminatory than humans.
- what purposes are served by AI explainability, why explainability prevents machine learning from being used in certain critical applications, and the main regulatory requirements for explainability
- what does "meaningful human control" of AI systems mean, and why is it important?
- what are the key elements of AI governance and accountability within corporations? What is an AI risk assessment?
- the legal framework around AI: the European General Data Protection Regulation (GDPR), Platform Regulation, the European AI Act, EU Charter of Fundamental Rights

Teaching will be structured around use cases, including autonomous lethal weapons, autonomous vehicles, facial recognition, social media use of algorithms, algorithms to detect terrorist risk; use of AI in criminal justice; use of AI in the workplace (recruiting, talent management)

PART 2-3

Generalization Properties of Algorithms in ML

Also known as - *Statistical Machine Learning and Convex Optimization*

2023

Instructors: A. Dieuleveut and H. Hendrikx.

Credits: 6ECTS (DS Master).

Syllabus: The majority of learning problems are formulated as optimization problems. optimization problems, based on the observation of a data sample (training set). Optimization of an objective defined on the basis of this sample makes it possible to propose an estimator that has good performance on the training set. However, we are generally interested in the estimator's estimator, i.e. its performance on a new observation. observation. With the emergence of large quantities of data since the 2000s, the link between the algorithm used and the generalizability of the associated estimator has become a major issue. Today, the question of generalization is still a major research issue, both in its theoretical and practical aspects. both theoretical and practical aspects. In this course, we focus on all the theoretical and heuristic results both theoretical and heuristic, to tackle this problem. More specifically, we will firstly, we will study the various approaches that enable us to obtain theoretical guarantees theoretical guarantees for the generalization of algorithms, in particular approaches related to complexity, stability and early stopping methods (early stopping, stochastic approximation). In a second second part, we'll look at heuristic approaches and the differences (explained or observed) in the context of deep learning (non-convex and over-parametrized

Instructor: Aymeric DIEULEVEUT

Credits: 6ects

Grading: Quizz + Présentation d'article / projet.

Numerus clausus: 50

Language: English.

Prerequisites : connaissances élémentaires en optimisation convexe et statistiques. Avoir suivi le cours d'optimisation pour les data-sciences permettra de mieux cerner les différents algorithmes en jeu.

In short, this lecture aims at providing an overview of first order optimization with machine learning applications in mind. The course is composed of ten lectures.

1. Lecture 1: introduction to SML. Risk relaxation, Rademacher complexity.
Take away: Understand the tradeoffs between Optimization and Statistics for ML algorithms.

2. Part I: Deterministic first order optimization

- (a) Lecture 2: Convex Optimization (deterministic). (GD)
- (b) Lecture 3&4: Acceleration, proximal, mirror descent.
- (c) Lecture 5. Performance estimation. A meta optimization point of view on worst case convergence guarantees

Take away:

Diving into first order optimization methods, from high level insights to theoretical guarantees and advanced algorithms.

**Advanced - Performance estimation - a meta optimization point of view on Optimization.*

3. Part II: Stochastic optimization and generalization of ML algorithms

- (a) Lecture 6: Stochastic Gradient descent 1. Non asymptotic convergence rates. Application to Machine learning: ERM of Risk minimization with Early stopping.
- (b) Lecture 7: Stochastic Gradient descent 2. Asymptotic convergence rates, Stochastic approximation etc.
- (c) Lecture 8: Case of Least-squares regression: Regularization (Tichonov, Early stopping), overparametrized setting, etc.
- (d) Lecture 9: Stability (Bousquet-Elyse)
- (e) Lecture 10: Lower bound on stochastic convex optimization.

Take away:

Understand stochastic optimization and SGD properties

Rethink generalization techniques and their links

**Insights on over-parametrized and Deep Learning regimes*

Advanced AI Methods for Graphs and NLP (ALTEGRAD)

Instructor: Michalis VAZIRGIANNIS

Credits: 6 ects

Grading: 20% from lab assignments and 80% from a data challenge

Language: English

Syllabus:

1. TEXT/NLP - Graph based Text Mining

- Graph-of-words GoWvis
- Keyword extraction (TFIDF, TextRank, ECIR'15, EMNLP'16)
- extractive summarization
- Sub-event detection in twitter streams
- graph based document classification: TW-IDF, TW-ICW, subgraphs abstractive summarization - ACL 2018 summarization

2. TEXT - NLP - Word & doc embeddings

- Word embeddings: word2vec-glove models, doc2vec, subword, Latent Semantic Indexing, context based embeddings
- doc similarity metrics: Word Mover's distance, shortest path kernels

3. Deep learning for NLP

- CNNs, RNNs LSTMs for NLP, text classification
- Meta-architectures
- Sequence to Sequence: Attention (HAN),
 - Domains: summarization
 - Translation, image captioning
- Unsupervised word sense detection/disambiguation
- French Linguistic resources: <http://master2-bigdata.polytechnique.fr/FrenchLinguisticResources/>

4. Graph kernels, community detection

Grakel python library: <https://github.com/ysig/GraKeL/>

5. Deep Learning for Graphs - node classification

- node embeddings (deepwalk & node2vec) for node classification and link prediction
- Supervised node embeddings (GCNN, ...)

6. Deep Learning for Graphs - Graph classification, GNNs

- graph CNNs
- message passing
- Graph - Auto-encoders

7. Sets embeddings - point clouds

8. Network Architecture Search - interpretability.

Prerequisites : Good level in Machine and Deep Learning, basic graph algorithms, python programming

PART 3

Causal Inference

Instructor: Marianne Clausel

Credits: 3 ECTS

Numerus Clausus : 50

Grading: Exam (50%), Project (50%). It could be more practical with a data analysis or presentations based on recent research papers.

Syllabus : In machine learning, there has been great progress in obtaining powerful predictive models, but these models rely on correlations between variables and do not allow for an understanding of the underlying mechanisms or how to intervene on the system for achieve a certain goal. The concepts of causality are fundamental to have levers for action, to formulate recommendations and to answer the following questions: "what would happen if » we had acted differently?

The questions of causal inference arise in many areas (socio-economics, politics, psychology, medicine, etc.): depending on the context which drug to use to improve the patient's health? what marketing strategy for product placement should be used to influence consumer buying behavior, etc. The formalism of causal inference makes it possible to study these questions as a problem of classical statistical inference. The gold standard for estimating the effect of treatment is a randomized controlled trial (RCT) which is, for example, mandatory for the authorization of new drugs in pharmaceutical and medical research. However, RCTs are generally very expensive in terms of time and financial costs, and in some areas such as economics or political science, it is often not possible to implement an RCT, for example to assess the effectiveness of a given policy.

The aim of this course is to present the available methods to perform causal inference from observational data. We focus on both the theoretical framework and practical aspects (available software solution). In terms of application, the lecture will be illustrated with recent exemples mainly in the field of health : What is the effect of Hydrochloroquine on survival ? What would have happened if Italy's government had waited a week before imposing lockdown measures ? Ect.

Topics covered:

- The Neyman-Rubin potential outcome causal model for observational studies
- Matching, propensity scores
- Efficiency and double robustness, double machine learning
- Estimating treatment effect heterogeneity, causal forest
- Causal discovery : causal models, graphical models and markov conditions

Online Learning and Aggregation

Instructor: Alexandre Tsybakov

Credits: 3 ects

Grading: Final exam

Language: English

Syllabus: The aim of online learning is to provide efficient recursive algorithms of prediction when the data are arriving sequentially in a streaming way rather than as an array given once and for all. Whereas statistical learning is dealing with independent identically distributed data, the emphasis in online learning is on adversarial setting where the data are of arbitrary nature satisfying mild conditions. In this setting, one of the key ideas is to use, at each time instance, a suitable randomized choice from the given set of candidate predictors. Analogous techniques can be applied to solve the problem of aggregation, that is, to obtain procedures that predict almost as good as the best estimator in a given set. This course provides an introduction to online learning and aggregation focusing on theoretical aspects.

Topics covered:

- Online classification in realizable case, halving.
- Online gradient descent for convex and strongly convex loss. Online-to-batch conversion. Online linear regression.
- Randomization by exponential weighting. Prediction with expert advice.
- Adversarial multi-armed bandit problem.
- Aggregation of estimators.
- Gradient-free online learning. Continuum bandit problem.

Operations Research for Data Science

Instructor: Zacharie Arles

Credits: 3 ects

Grading: Examen écrit et projet

Language: French

Syllabus: Ce cours présente les principales applications de la recherche opérationnelle aux sciences des données.

- Séance 1 - Régression linéaire par résolution d'un problème d'optimisation robuste

Le problème de régression linéaire est très majoritairement résolu en introduisant un terme de biais dans l'objectif permettant d'éviter le sur-apprentissage. Dans cette séance nous verrons qu'il peut être plus efficace de considérer une modélisation robuste du problème dans laquelle on cherche à minimiser l'erreur pour la pire incertitude possible sur les données.

- Séance 2 - Arbres de décision et de régression optimaux

Les arbres de décision sont des classifieurs interprétables très populaires. Ils sont généralement entraînés en utilisant des algorithmes gloutons tels que CART. Nous présentons différents programmes linéaires en nombres entiers permettant d'obtenir des arbres de décisions optimaux.

- Séance 3 - Optimisation interprétable

Il est généralement difficile de déterminer pourquoi une solution est optimale pour une instance donnée et pas pour une autre. L'objectif de cette séance est de présenter une méthode permettant de déterminer un classifieur interprétable capable d'associer une solution (idéalement optimale) à une instance.

- Séance 4 - Analyse en composantes principales parcimonieuse

L'ACP permet d'obtenir des composantes représentant au mieux la variabilité d'un ensemble de données. Cependant, ces composantes sont peu interprétables car tous leurs coefficients sont généralement non nuls. Pour pallier cela, on modélise dans cette séance le problème d'obtention de composantes interprétables que l'on résout par un branch-and-bound.

- Séance 5 - Explications contrefactuelles optimales

Dans le cadre de la classification supervisée, l'explication contrefactuelle consiste à déterminer la plus petite modification des caractéristiques d'une donnée permettant de changer sa prédiction. Cela peut par exemple permettre à un client à qui on a refusé un prêt de comprendre les raisons de ce choix et de savoir les changements qu'il doit effectuer pour espérer l'obtenir. Lorsque la prédiction est effectuée par une forêt d'arbre de décision, nous verrons que ce problème peut se modéliser par un PLNE.

- Séance 6 - Examen

Prerequisites : Avoir suivi un cours de recherche opérationnelle couvrant : théorie des graphes, simplexe et branch-and-bound.

Cloud Data Infrastructure

Instructor: Nicolas Travers

Credits: 3 ects

Grading: Project on real use cases, 5 deliveries

Numerus clausus: 40

Language: English

Syllabus: This course aims at describing how to model and distribute data efficiently in a distributed infrastructure dedicated to large-scale data management. The students will study techniques of denormalization, optimization of queries via modeling, sharding and indexing, information system constraints (consistency, persistence, distribution, etc.), and compare existing solutions and their specificities. The course will allow students to integrate the NoSQL eco-system for data management and to make relevant choices of adequate data infrastructure according to their own query needs.

Main themes :

- Learn data distribution/replication strategies & Compare replication algorithms (HDFS, DHT, GridFS),
- Distributed concurrency and consistency issues & algorithms (CAP, PACELC, 2PC, Paxos)
- Data modeling in a distributed context (NoSQL data families, cloud cost models)
- IS conception process over the Cloud

Recommended readings:

- T. Özsu, P. Valduriez, Principles of Distributed Database Systems, **4th Edition**, Springer (2020)

Prerequisites: Database (E/R, SQL), basic knowledge in database optimization, UML class diagrams and notions in networks.

Cooperative Optimization for Data Science

Instructor: Andrea Simonetto

Credits: 3 ects

Grading: Project and written exam

Language: English

Syllabus:

The course presents continuous optimization techniques that have been developed to deal with the increasing amount of data. In particular, we look at optimization problems that depend on large-scale datasets, spatially distributed data, as well as local private data.

We will focus on three different aspects: (1) the development of algorithms to decompose the problem into smaller problems that can be solved with some degree of coordination; (2) the trade-off of cooperation vs. local computation; (3) how to design algorithms that ensure privacy of sensitive data.

#1 Class. Introduction: recap on convex models and algorithms. A model for a network of communicating and computing nodes. Parallel methods in optimization: Gauss method, Jacobi method, incremental methods. Consensus optimization problem.

#2 Class. Distributed optimization (I): primal methods: gradient and gradient tracking. Communication vs. computation trade-off, network scaling.

#3 Class. Distributed optimization (II): dual methods: dual decomposition, ADMM; primal-dual methods and networked problems. Possible example in large-scale smart grids.

#4 Class. Federated optimization (I): the setting and the problem, its relation with distributed optimization and the main differences. Federated averaging and other momentum-based first-order algorithms.

#5 Class. Federated optimization (II): Robustness, Communication vs. computation trade-off, network scaling, relaxations, acceleration, personalization. Possible example with real-data.

#6 Class. Privacy issues in optimization: the concept of privacy and how to enforce it. Differential privacy

Deep Learning II

Instructor: Yohan Petetin

Credits: 3 ects

Grading: Session 1 : project - Session 2 : project 30% + writing exam 70%

Language: English

Syllabus: Ce cours présente les architectures de type "réseaux de neurones profonds" qui ont permis, ces dernières années, de grandes avancées pour des problématiques de classification, de prédiction ou de détection. Il s'agit de la suite du cours 'Deep Learning I' de la première période et ce cours se focalisera avant tout sur les fondements et la compréhension théorique de modèles dits **génératifs** tels que les "Restricted Boltzmann Machines (RBM)", "Deep Belief Network (DBN)", "Generative Adversarial Network (GAN)" ou encore les "Graph Neural Networks" qui permettent le traitement de graphes de données. Les étudiants seront également amenés à implémenter ces modèles dans le langage de leur choix.

Planning

- Rappel des méthodes d'échantillonnage de type Monte Carlo (principe, échantillonneur de Gibbs);
- Restricted Boltzmann Machine (Définition, propriétés, théorème d'universalité, apprentissage par l'algorithme Contrastive Divergence);
- Deep Belief Network (Définition, apprentissage);
- Auto-encodeurs variationnels (l'approche variationnelle, les auto-encodeurs);
- Generative Adversarial Network (Principe, universalité, extensions);
- Graph Neural Networks (principe, applications)

Audio and Music Information Retrieval

Instructor: Geoffroy Peeters, Gael Richard

Credits: 6 ects

Grading: 30% labs/project + 70% written exam

Language: English

Syllabus: Audio and Music information retrieval is the interdisciplinary research field related to the extraction of semantic information from the audio signal; it allows the development of applications such as speech/music segmentation, recognition (environmental sound classification, acoustic scene classification, musical instrument recognition), source separation, the estimation of specific music attributes (multi-pitch, tempo/beat, chord, structure), music identification by fingerprint (à la Shazam), cover detection or auto-tagging (into genre, mood)

This course presents the different facets of this field ranging from audio signal representation (Fourier, STFT, Constant-Q transform, audio features), music representation (pitch, chords, rhythm, structure), to pattern-matching and machine-learning models (DTW, HMM, generative/discriminative learning and deep learning).

Planning : 10 sessions of 4 hours + Exam

Big Data and Insurance Project

Instructor: Denis Oblin

Credits: 3 ects

Grading: business case and oral presentation by team

Language: This course will be given in english or french with lecture material in french.

Syllabus: the objective of this course is to provide an insight of a specific industry and understand how data is leverage in this context. The course mix présentations (on insurance industry, uses cases, project management insight) and testimony from insurance actors : established insurance company or start ups. You will have to identify a possible usecases and promote it to c-levers :

Course overview:

1) presentations:

- insurance industry insight
- how to find the question ? (not the easy part !)
- project management
- use cases & insurtech

2) 2-3 live testimony (to be updates), in french

Structured Data : Learning and Prediction

Instructor: Florence d'Alché-Buc

Credits: 3 ects

Grading: Project defense

Numerus clausus : 50

Language: English

Syllabus: Many real-world applications involve objects with an explicit or implicit structure. Social networks, protein-protein interaction networks, molecules, DNA sequences and syntactic tags are instances of explicitly structured data while texts, images, videos, biomedical signals are examples with implicit structure. The focus of the course is solving learning and prediction tasks under this complex/structured assumption. While in learning and prediction problems the case of structured inputs has been investigated for about three decades, structural assumption on the output side is a significantly more challenging and less understood area of statistical learning. This course provides a transversal and comprehensive overview on the recent advances and tools for this exploding field of structured output learning, including conditional random fields, max margin approaches, surrogate approaches as well as end-to-end deep learning. These approaches illustrated on real applications will allow to cope with complex problems such as music transcription, question-answering, automatic captioning, molecule identification.

Tail Events Analysis: Robustness, Outliers and Models for Extremes

Instructor: Pavlo Mozharovskyi

Credits: 3 ects

Grading: written exam

Language: English

Syllabus: Analysis of events in the tail of the distribution constitutes an important topic in statistics. The aim of the course is threefold: construction of the estimators less sensible to contamination of the data, identification of the outlying observations, and modeling of extreme events. The course starts with the introduction to robust statistics and measures of robustness where the concepts of the influence function and of the breakdown value are given. Then, the simplest univariate robust estimators of location, scale, and skewness are regarded which behave consistently even if the data is contaminated. These are further generalised to robust estimators of multivariate location and scatter (Stahel-Donoho estimator, minimum covariance determinant estimator, S-estimators, MM-estimators). Robust regression as well as PCA estimators are also considered. An important notion in robust statistics—data depth—is then introduced for the multivariate and functional framework. Presentation of the concept of the data depth function is followed by studying most important depth notions such as Tukey or projection depth, and (multivariate) functional depths. The regarded above material is then applied to detection of outliers in multivariate and functional data, as well as the cell-wise outliers. Finally an introduction to extreme values analysis is given. Here, extremes are defined as the largest values of a considered dataset. Extreme value theory suggests natural models for block-maxima and excesses above large thresholds, which give rise to estimates of quantities of major interest for risk management, such as high quantiles, large return levels, or tail probabilities outside the range of observed data. This aims on providing guidelines to the students for applying extreme value models to answer such practical questions.

Format: 6 × 3.5 hours + exam

Planning:

Week 1: Introduction to robust statistics. Measures of robustness: influence function, breakdown value. Univariate robust estimators of location, scale, skewness. Multivariate location and scatter estimators. Robust regression and robust PCA. Reading: Rousseeuw and Leroy (1987), chapters 1–3; Huber and Ronchetti (2009), chapters 1, 3, 8, 11; Wilcox (2016), chapters 1–3, 10; Rousseeuw and Driessen (1999); Hubert et al. (2005).

Week 2: Lab session I. Univariate robust estimation. Robust multivariate estimation: projection pursuit, minimum covariance determinant estimator. Robust regression and ROBPCA.

Week 3: Multivariate data depth. Statistical data depth function: definition and properties, chosen notions. Identification of multivariate (row-wise and cell-wise) outliers. Reading: Becker et al. (2013),

chapters 1, 2, 4; Wilcox (2016), chapter 6; Tukey (1975); Donoho and Gasko (1992); Zuo and Serfling (2000); Hubert et al. (2015); Rousseeuw and Bossche (2018).

Week 4: Data depth definition for non-Euclidean spaces. Data depth in infinite-dimensional setting. Identification of functional and curve outliers. Reading: Fraiman and Muniz (2001); López-Pintado and Romo (2009); Claeskens et al. (2014).

Week 5 : Extreme value statistics. The one dimensional case, distribution of maxima of large datasets, excesses above high thresholds. Inference methods and case studies. Multi-dimensional setting. Regular variation. Reading: Coles et al. (2001); Beirlant et al. (2006); Resnick (2013); De Haan and Ferreira (2007); Resnick (2007, 2013).

Week 6: Lab session II. Data depth: Tukey, projection, spatial depths, functional depths, applications to outlier detection. Extreme value analysis: return levels, probabilities of failure.

Optimal Transport: Theory, Computations, Statistics, and ML applications

Instructor: Marco Cuturi

Credits: 3 ects

Grading:

Language: English

Syllabus: 8 séances de cours + 4 séances de TD = 18 heures

3 hours: theory

- Monge and Kantorovich Problems, duality in OT.
- 2-Wasserstein geometry and the Brenier theorem. Applications to transport between Gaussians
- Transport in 1D
- Wasserstein space: JKO flow.

7.5 hours: computations and statistics

- Algorithmic overview: network flow solvers in the discrete world, Benamou-Brenier formula in the PDE world.
- Statistical results and the curse of dimensionality
- Regularized approaches to compute optimal transport.
- Differentiation of Optimal transport: unrolling / implicit.
- Unbalanced generalizations, quadratic extensions (GW).

2 TDs:

- 1D transport, transport between Gaussians
- Network flow solver type algorithms + Sinkhorn algorithm

3 hours: applications

- Handling measures with the Wasserstein geometry: barycenters, clusters
- Wasserstein GANs
- Applications to Biology (cell pathways) and NLP (alignment of multilingual corpora)

2 TDs:

- Differentiation of Sinkhorn's algorithm
- Transport between high-dimensional point clouds.

CAPSTONE Project

Instructors: Marylou Gabrié & Anna Korba

Credits: 6 ects

Grading: Final report and presentation

Language: English

Syllabus: The Data Science Capstone project provides an opportunity for students to carry out a defined piece of independent research or design, on a subject proposed by an industrial ~~or research~~ partner. The skills it aims at developing include the capacity to define a research or design question, the ability to relate practical problems to existing knowledge and carrying out the research or design in a systematic manner.

Students will work in groups. Group sizes (~~between 3 and 5~~) will depend on the project. The list of available projects will be provided to the students in October. Each group will be supervised by the industrial contact proposing the project. The results will be presented in a final project presentation and a report.

Machine Learning research seminar

Instructor: Éric Moulines - Rémi Flamary

Credits: 6 ects

Grading:

Language: English

Syllabus: Research in machine learning has grown exponentially in recent years, revealing many promising and successful research directions. In this seminar, we will select and discuss a number of topics from the current research. In this seminar, students will be able to familiarize themselves with current research in machine learning, explore new areas and ideas, and analyze and critique recent publications.

To this end, each student will be given 2-5 research papers to read and analyze carefully. From these, they are to explore the surrounding literature and summarize their findings, criticisms, and research ideas in a 4-page paper (double-spaced).

Students will then review each other's papers to provide valuable feedback and critique. Finally, all students will prepare 25-minute presentations and present their work in a block seminar at the end of the semester.

3 research seminars will be organized where students will be able to attend research presentations given by experienced researchers who will present new results and organize a discussion with the students.

We will cover the following topics:

- learning theory
- deep learning (architectures, deep learning theory, etc.)
- major applications of deep learning.
- optimal transport
- generative models
- reinforcement learning
- Optimization
- federated learning
- learning/economy interfaces
- Probabilistic ML

Representation Learning for Computer Vision and Medical Imaging

Instructor: Pietro Gori et Loïc Le Folgoc

Credits: 3 ects

Grading: Grading will be based on the practical session reports (50%) and written or oral exam (depending on the number of students) (50%)

Language: English

Syllabus: 7 lectures divided into 1,5h of theory and 1,5h of practical session.

Description:

Good and expressive data representations can improve the accuracy of machine learning problems and ease interpretability and transfer. For vision tasks, handcrafting good data representations, a.k.a. feature engineering, was traditionally hard. Deep Learning has changed this paradigm by allowing us to automatically discover good representations from data. This is known as representation learning. The objective of this course is to introduce representation learning in computer vision and medical imaging applications.

We will cover the following topics:

- Introduction to Representation Learning for Vision
- Transfer Learning and Domain Adaptation
- Self-supervised and Contrastive Learning
- Knowledge Distillation
- Disentangled Representations
- Conditional Generative models
- Attention and Transformers
- Visualization and interpretability in Neural Networks
- Multimodal representation learning and Foundation models

Recent Developments in Responsible AI

Instructor: Charlotte LACLAU – Florence D’ALCHE-BUC

Credits: 3 ects

Grading: Students will be asked to write a blogpost article on a paper recently published at a highranking conference (eg. ICLR, NeurIPS) related to the topic of the course. A list of selected articles will be proposed by the lecturers. Blogposts will be published on the medium account of the master.

Language: English

Syllabus: Artificial intelligence, as a transversal discipline, plays a central role in our modern society, driving vital advances and amplifying efficiency, well-informed decision-making and general practicality in our daily routines. This advanced master's course aims to provide students with a comprehensive understanding of the latest developments in Responsible AI. The course will explore various facets of Responsible AI, including interpretable AI, fairness in machine learning, robust machine learning, data privacy, and frugality. Students will delve into both theoretical foundations and practical implementations, equipping them with the skills to design and implement AI systems that are ethical, accountable, and aligned with societal values.
